should we make this a minimise/maximise thing? similar to hevy app
actually, lets keep this static, but the list is scrollable
lets make these buttons float, disappear on scroll and re-appear on scroll stop/reach bottom of list

Settle-Up
Add each player's buy-in and final balance.
Player name
Numbers don't add up
Final balances exceed buy-ins by $32123
Total buy-ins: $32121
Delta: $321321
Auto-resolve discrepancy
How does this work?

Settle Up
New Game

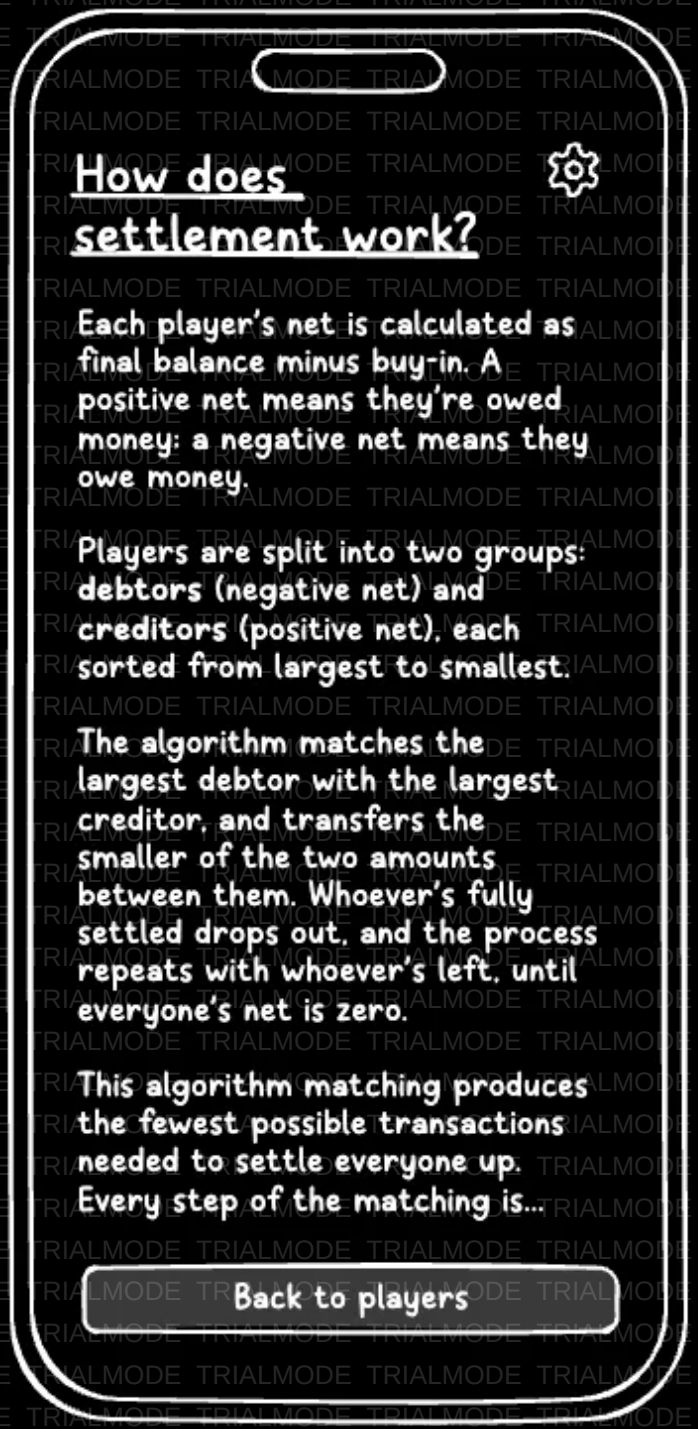

When buy-ins and final balances don't quite match, the leftover amount (the delta) gets split evenly across every player's final balance.

Positive delta (balances too high): a small amount is deducted from each player's payout.
Negative delta (balances too low): a small bonus is added to each player's payout.

If splitting the delta would push someone's balance negative, they're excluded and their share moves to the rest — which can cascade if others are close to zero too. If it cascades until no one's left to absorb it, auto-resolve isn't offered and you'll need to fix the entry manually.

The split is always even across players, not weighted by buy-in size, and every resolution is shown in the calculation breakdown so nothing happens silently.

Each player's net is calculated as final balance minus buy-in. A positive net means they're owed money; a negative net means they owe money.

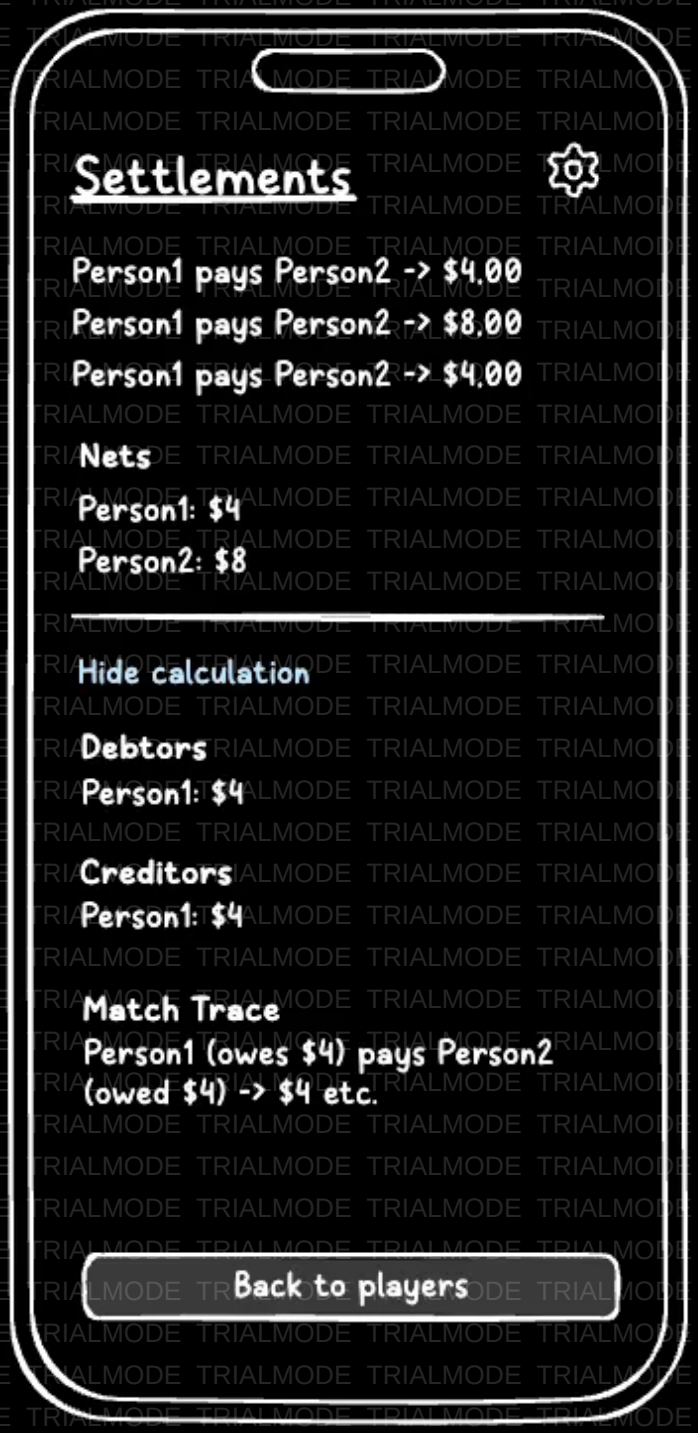

Players are split into two groups: debtors (negative net) and creditors (positive net), each sorted from largest to smallest.

The algorithm matches the largest debtor with the largest creditor, and transfers the smaller of the two amounts between them. Whoever's fully settled drops out, and the process repeats with whoever's left, until everyone's net is zero.

This algorithm matching produces the fewest possible transactions needed to settle everyone up.
Every step of the matching is recorded, so you can see exactly who paid whom and why in the calculation breakdown.

Each player's net is calculated as final balance minus buy-in. A positive net means they're owed money; a negative net means they owe money.

Players are split into two groups: **debtors** (negative net) and **creditors** (positive net), each sorted from largest to smallest.

The algorithm matches the largest debtor with the largest creditor, and transfers the smaller of the two amounts between them. Whoever's fully settled drops out, and the process repeats with whoever's left, until everyone's net is zero.

This algorithm matching produces the fewest possible transactions needed to settle everyone up.
Every step of the matching is recorded, so you can see exactly who paid whom and why in the calculation breakdown.
